

unnamedHid

General purpose HID middleman for fun features

Imagine the famous omw →
On my way! correction on every device

```
#include <Arduino.h>
#include <pio_usb.h>
#include "USBHIDKeyboard.h"

USBHIDKeyboard DeviceKeyboard;

String inputBuffer = "";

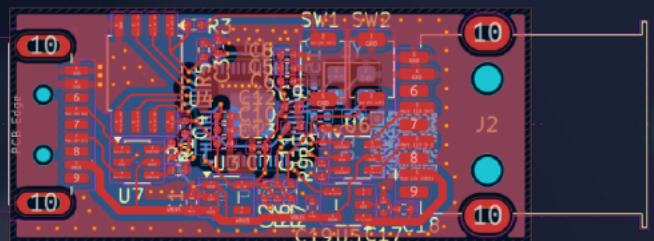

void handle_keyboard_report(uint8_t dev_addr, uint8_t idx, uint8_t len) {
    if (len < 8) return;

    static uint8_t prev_keys[8] = {0};
    uint8_t const* keys = report + 2;

    for (int i = 0; i < 8; i++) {
        uint8_t key = keys[i];
```

A multipurpose HID middleman based on a RP2040. Anything from **rubber ducky** scripts to word-to-phrase replacements are supported

But wait! Doesn't RP2040 only have one USB PHY?
Turns out you can bit bang it with PIO! Enjoy programming macros to turn "banana" into "apple" or make it spam "Iarp". The choice is yours.
